

# Presentation

## The React Framework for the Web

Used by some of the world's largest companies, Next.js enables you to create high-quality web applications with the power of React components.

**SAMREEN**

# NEXT.JS

# TABLE OF CONTENT

- ❖ 01- What is the page.tsx file.?
- ❖ 02- What is the layout.tsx file?
- ❖ 03- What is the Link tag, why do we use this tag, and what is its purpose?
- ❖ 04- How can we create nested pages in Next.js?
- ❖ 05- What are components, and why do we use them?
- ❖ 06- How can we apply CSS in Next.js?
- ❖ 07- What is Tailwind CSS, and what are the differences between Tailwind CSS and standard CSS?

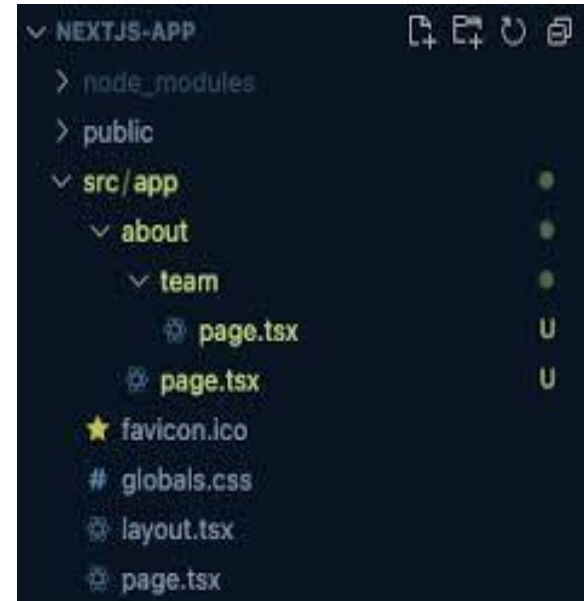

# 1. What is page.tsx file?

## Definition:

The page.tsx file is a special file in Next.js that defines a route. Each file in the app directory corresponds to a route in the application.

## Purpose:

It contains the React component that renders the content for that specific route.

## 2. What is layout.tsx file?

### Definition:

The layout.tsx file is used to define the layout structure for your pages.

### Purpose:

It allows you to apply consistent UI elements (like headers, footers, sidebars) across multiple pages without duplicating code.

```
app
├── dashboard
│   ├── layout.tsx
│   ├── settings
│   │   └── page.tsx
│   └── analytics
│       └── page.tsx
```

# 3- What is the Link tag?

## Definition:

The `<link>` tag **defines the relationship between the current document and an external resource.**

The `<link>` tag is most often used to link to external style sheets or to add a favicon to your website. The `<link>` element is an empty element, it contains attributes only.

## Example:

**`import Link from 'next/link';`**

**`<Link href="/about">About Us</Link>`**

A code editor window with a dark blue background and light green text. It shows a Next.js page component using the Link component. The code is as follows:

```
1 import Link from "next/link";
2
3 export default () => {
4   <div>
5     Hello World.{ " "}
6
7     <Link
8       href={{
9         pathname: "/about",
10        query: { name: "Ruben" }
11      }}
12    >
13      <a>About</a>
14    </Link>
15  </div>
16 };
17
```

# What are the Purpose of the Link tag?

## Client-Side Navigation:

The <Link> component allows for seamless navigation without a full page reload. This enhances user experience by making transitions faster.

## Prefetching:

Next.js automatically prefetches linked pages when they come into view (if the user is on a page long enough). This means that the linked page is already loaded in the background, making navigation instantaneous.

**Accessibility:** The <Link> component handles accessibility concerns, such as ensuring that the linked elements are keyboard navigable.

## CLIENT-SIDE RENDERING

# 4- How to Create Nested Pages in Next.js?

Next.js uses file-system routing where folders are used to create *nested* routes. Each folder represents a route segment that maps to a URL segment. `page.tsx` is a special Next.js file that exports a React component, and it's required for the route to be accessible. In your application, you already have a page file: `/app/page.tsx` - this is the home page associated with the route `/`. `/app/dashboard/page.tsx` is associated with the `/dashboard` path.

# 5- What are the Components

Components allow you to build self-contained, reusable snippets of code. you can take these individual bricks and combine them together to form larger structures.

Next.js components are essentially React components. They can be functional or class-based and are used to define how a part of the UI should appear and behave.

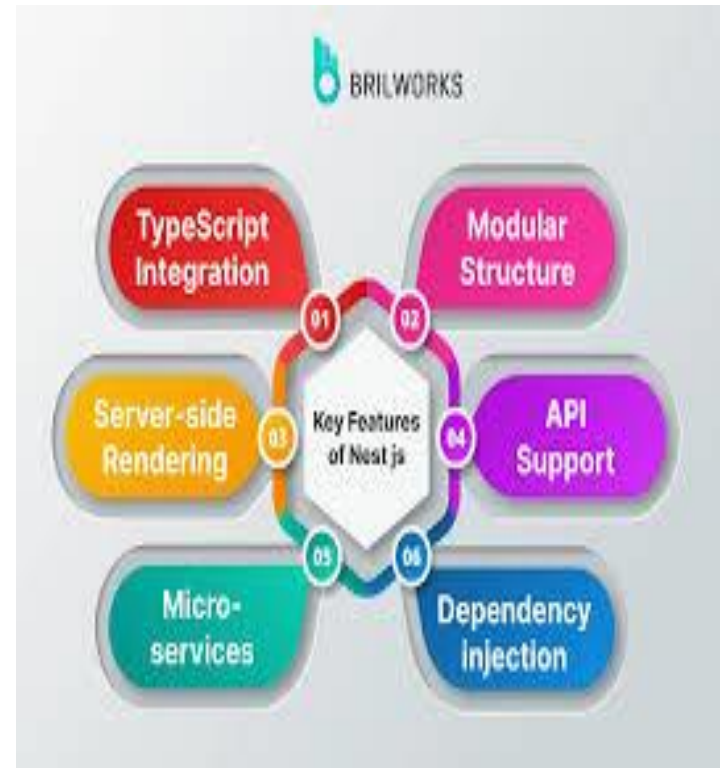

# Why Use Components in Next.js?

## Reusability:

Components can be reused across different pages and parts of the application, making your code DRY (Don't Repeat Yourself).

## Organization:

Breaking your UI into components helps keep your code organized and manageable, allowing for easier navigation and maintenance.

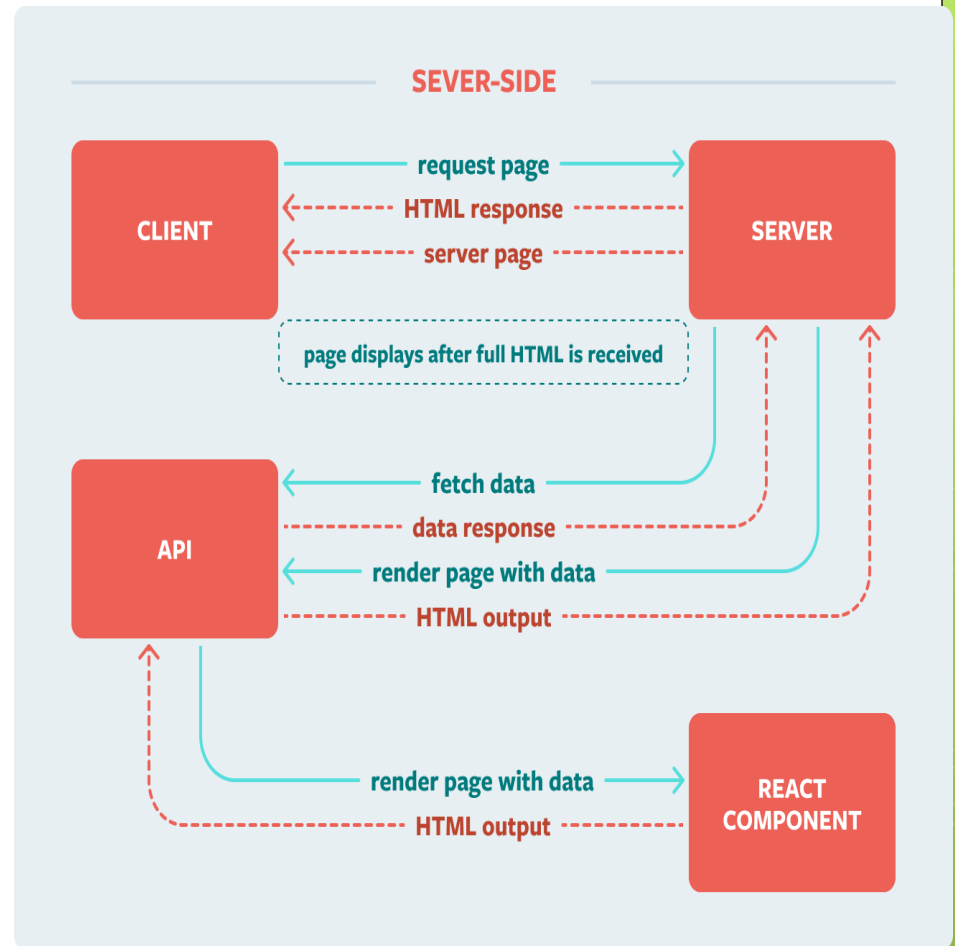

# Use Components in Next.js?

## Separation of Concerns:

Components can encapsulate specific functionality, separating the logic of a UI element from other parts of the application. This makes it easier to understand and test each component in isolation.

## Dynamic Rendering:

Next.js components can leverage features like Server-Side Rendering (SSR) and Static Site Generation (SSG), allowing you to create dynamic, fast-loading applications that are optimized for performance and SEO.

global.css U x

```
1  :root {
2    --color-primary: #da3654;
3    --color-text: #000;
4    --color-text-2: #3c4856c2;
5  }
6
7  @font-face {
8    font-family: "Recoleta";
9    src: url("https://bejamas.i
10 }
11
12 body {
13   margin: 0;
14   font: 100%/1.55 "Poppins", s
15   scroll-behavior: smooth;
16 }
17
18 :is(h1,h2,h3,h4) {
19   font-family: "Recoleta", "P
20 }
21
```

## 6- How can we apply CSS in Next.js?

In Next.js, you can apply CSS in several ways, allowing for flexibility depending on your project needs. Here are some common methods:

### Global CSS

To include global styles, you can create a CSS file and import it in your `_app.js` file:

- Create a CSS file in the styles directory (e.g., `styles/global.css`).
- Import the CSS file in your `pages/_app.js`:

# ❑ CSS Modules

CSS Modules allow you to write scoped styles. This means styles defined in a module are specific to the component, preventing naming conflicts.

Create a CSS Module file with the `.module.css` extension (e.g., `styles/Home.module.css`).

Import the CSS Module in your component:

Shown in side image:

```
import classes from './file.module.css'
```

```
<div className={classes.filters}>
```

```
  filter component
```

```
</div>
```

# □ Styled JSX

Next.js supports styled-jsx out of the box, which allows you to write scoped CSS directly within your components.

## javascript

```
function Home() {  
  return (  
    <div>  
      <p>Hello, World!</p>  
      <style jsx>`  
        p {  
          color: blue;  
        }  
      `</style>  
    </div>  
  );  
}
```

export default Home;

```
index.js  x  
1  var React = require('react');  
2  var ReactDOM = require('react-dom');  
3  require('./index.css');  
4  
5  // state  
6  // lifecycle event  
7  // UI  
8  
9  class App extends React.Component {  
10   render() {  
11     return ( <  
12       div >|  
13       Hello World!  
14       <  
15       /div>  
16     )  
17   }  
18 }
```

# ❑ Styled Components

You can also use popular CSS-in-JS libraries like Styled Components. First, install the library:

npm installed styled-components

Then, create styled components:

```
import styled from 'styled-components';  
const Container = styled.div` color:red;`;  
function Home() {  
  return <Container>Hello, World!</Container>;  
export default Home;
```

# Tailwind CSS

Next.js can easily integrate with Tailwind CSS for utility-first styling. To set it up, follow these steps:

## Install Tailwind CSS:

```
npm install tailwindcss  
postcss autoprefixer  
npx tailwindcss init -p
```

In your `globals.css`, add the Tailwind directives.

```
/* styles/globals.css */  
@tailwind base;  
@tailwind components;  
@tailwind utilities;
```

```
<div class="p-6 max-w-sm mx-auto bg-white rounded-xl shadow-lg flex items-center sp  
<div class="shrink-0">  
    
</div>  
<div>  
  <div class="text-xl font-medium text-black">ChitChat</div>  
  <p class="text-slate-500">You have a new message!</p>  
</div>  
</div>
```

# What is Tailwind CSS?

## Tailwind CSS

is a utility-first CSS framework that allows developers to build custom designs quickly and efficiently. Unlike traditional CSS frameworks that provide pre-designed components, Tailwind focuses on offering low-level utility classes that can be combined to create unique designs directly in your markup.

# Differentiate b/w the Tailwind CSS & Standard CSS.

| S. # | TAILWIND CSS  | STANDARD CSS  |
|------|---|---|
| 01   | <b>Utility-First Approach</b><br>Tailwind CSS uses a utility-first approach, providing small, reusable utility classes for styling directly in your HTML.   | <b>Utility-First Approach</b><br>This contrasts with standard CSS, where styles are usually defined in separate stylesheets.                                  |
| 02   | <b>Customization</b><br>Tailwind is highly customizable through a configuration file, allowing developers to define theme colors, spacing, and breakpoints. | <b>Customization</b><br>Standard CSS requires manual adjustments for each project.  |
| 03   | <b>Readability</b><br>Tailwind can improve readability by making the styles explicit within the markup.   | <b>Readability</b><br>Standard CSS often requires looking up styles in separate files, which can make it harder to understand the overall design at a glance. |
| 04   | <b>Development Speed</b><br>Using Tailwind can speed up development by reducing the need for custom class names and allowing for rapid prototyping.         | <b>Development Speed</b><br>Standard CSS may require more setup and boilerplate code.   |
|      |   |   |
